## A Data and Sample

A major contribution of this paper is the construction of an original dataset comprehensively describing student homelessness in New York City. Given NYC's outsized importance in the realm of family homelessness-along with the extensive detail of linked longitudinal administrative data - this represents perhaps the richest portrait of student homelessness in the U.S. to date. The data comes from two key sources: the NYC Department of Homeless Services (DHS) and the NYC Department of Education (DOE). In this section, I summarize key data management steps. Additional information about the DHS data can also be found in Cassidy (2020).

## A. 1 DHS Data

The DHS portion of the data constitutes the core sample: all eligible families with children entering shelter from January 1, 2010 to December 31, 2016. ${ }^{1}$ These records, which contain details about families' compositions, demographics, and conditions of shelter entry, as well as basic identifying information, are extracted from DHS' Client Assistance and Rehousing Enterprise System (CARES), which is the City's management information system for homeless services. This "sample" is essentially a census, excluding only those (rare) individuals with missing data on critical identifying variables.

CARES contains individual-level records for each family member. In Cassidy (2020), I rework this data so that the unit of observation becomes the family-spell. That is, there is one observation per family per shelter stay, with new spells defined as those occurring more than 30 days subsequent to the end of a previous stay. ${ }^{2}$

The DHS data contains rich information about families and their shelter stays, most of which comes from the Temporary Housing Assistance (THA) applications families fill out to apply for shelter. Variables include basic identifying information (e.g., name, date of birth), family relationships, the presence of health issues (physical, mental, or substance abuse), official shelter eligibility reason, and housing history (most recent address prior to application). Shelter stay attributes, including facility type, address, and dates of stay, come from "Lodge History" extracts, a separate CARES query.

The data is collected primarily for management rather than analysis, and so requires extensive processing to be econometrically coherent. Key data management steps include: defining shelter spells (including length of stay calculations), geocoding addresses, and defin-

[^0]ing analytical variables (e.g., discrete variables summarizing eligibility reasons or counting family members), some of which are assembled across observations.

I augment this core DHS data by linking it to administrative records maintained by other agencies. I obtain information on public benefit use - Cash Assistance (i.e., CA, public assistance or "welfare," consisting of federal Temporary Assistance for Needy Families (TANF) and New York State (NYS) Safety Net Assistance (SNA)) and the Supplemental Nutrition Assistance Program (i.e., SNAP or "Food Stamps") —from the Department of Social Services (DSS), using probabilistic matching techniques based on Social Security Number (SSN), first name, last name, and date of birth. The DSS data also includes information on race and self-reported educational attainment. In a similar fashion, the NYS Department of Labor (DOL) provides data on quarterly employment and earnings, through a deterministic match on $\mathrm{SSN}^{3}$. To ease computational burden, the public benefit and labor matches are restricted to head of family. Because (a) most homeless families consist of a single adult and several children and (b) heads of case are most likely to appear in the benefit and labor data, this restriction should not meaningfully change the results relative to an exhaustive match of all family members.

For purposes of assessing family outcomes, as in Cassidy (2020), the natural unit of observation is the family-spell. In the present study, the underlying individual-level records come to the fore. From the CY2010-2016 CARES census, I cull the records of all individuals aged 4 to 21 during any point in their shelter stays. I choose these cutpoints because they represent the minimum (children can begin pre-K at age 4) and maximum (children can attend school through the school year in which they turn 21) ages individuals can be enrolled in DOE. ${ }^{4}$ In total, there are 89,337 unique such children. Using CARES' individual and family identifiers, I then relink these individuals to the family-shelter-spells of which they are a part. In this manner, the unit of observation becomes the individual-homeless-spell.

Several comments are in order regarding the definition of DHS-derived analytical variables. All covariates (see Tables A.4A-A.4B) are defined at the time of shelter entry (or as near as is possible). Person-specific variables, such as age, are defined at the individual level. Correspondingly, attributes shared by all family members, such as eligibility reason or shelter type, are defined at the family level. The exceptions are variables derived from DSS and DOL: CA, SNAP, employment, earnings, and level of education, which are defined by head of household but treated as "family-level" variables common to all members. Families that are not matched to DSS or DOL are assumed genuinely not receiving benefits or not

[^1]employed, respectively (though, due to the fuzzy nature of the match, there may be some false negatives). I take the extra step of creating an "unknown" education category for families that do not match DSS in order to include education as a covariate without restricting the sample. For a similar reason-avoiding unduly excluding families from the sample-I also create an "unknown" category for homeless eligibility reason, which is a DHS CARES variable missing for a handful of families. For earnings, I add one dollar before taking the natural log.

In sum, the DHS data consists of unique observations for each school-age child during each homeless spell experienced by their families, complete with all covariates, both individual and family-level, associated with each spell.

## A. 2 DOE Data

The second key data source are educational records maintained by DOE, spanning school years 2005-06 to 2016-17. It contains records for each student during each school year, with separate topical tables for June biographical information (demographics, student characteristics, and enrollment details, including school ID and attendance), test scores (3-8 grade state standardized tests and Regents for high schoolers), and graduation (for high schoolers). The biographical table is given the "June" designation because it is reconciled at the end of each school year, in June, and reflects each student's most up-to-date information as of then. For data size reasons - each table includes all public school students, not only homeless ones-there is a separate topical table for each school year. All variables are student-specific.

In addition to the topical tables, there is also a separate Transactions table detailing all admissions and discharges, including normative promotions (i.e., structural leveling up, as from elementary to middle school) as well as nonstructural school changes, during all school years in the sample. In contrast to the June biographical information, the Transactions table records the precise dates and reasons for each school change.

In practice, a fair amount of data processing must take place to shape the records into a form suitable for analysis. Key tasks include harmonizing variables across years (as available fields and definitions change over time) and linking a student's records (via unique student ID's) across topics and over time. The resulting dataset consists of a single observation for each student in each school year.

Key DOE variables used in the analysis are described in Section 3 and Tables A.4A-A.4B. As with the DHS data, some of these variables are not native to the administrative data, but rather are constructed from the underlying fields (e.g., test scores normalized by grade and year).

Of particular note, schools are identified by unique "DBNs," comprised of school district (D), school borough (B), and school number (N) codes. To facilitate measurement of school-shelter distances, I link these DBNs to publicly available school geocode files (covering school years 2012 to 2017), which, in addition to school names and addresses, contain X-Y coordinates as well as grade ranges (which are important for identifying nonstructural school changes).

## A. 3 Data Match

The matching procedure to link DHS' candidate homeless students with DOE records, performed with the assistance of the Mayor Office's Center for Innovation through Data Intelligence (CIDI) and DOE staff, follows standard City protocols for linking human service and education data. It uses The Link King version 9.0 (Campbell, 2018), a SAS application, with default settings and match records based on first name, last name, date of birth, and sex. The Link King uses a variety of sophisticated algorithms to deterministically and probabilistically match records across datasets. For details, see Campbell, Deck and Cox (2018). I accept match certainty levels 1 (highest possible) to 6 (low-moderate) as true matches, while level 7 (probabilistic maybe), along with unmatched records, are defined as non-matches. Close cases, including those with several match candidates, are reviewed manually. Once the match is complete, data is deidentified by stripping names and official identifiers and replacing them with scrambled student ID.

Given 12 years of education records and 7 years of homeless data, the match is overinclusive. There are three types of matched students: (1) children who are in school during their shelter stays, (2) adult family members (typically heads of household) who attended DOE schools at some time in the recent past, (3) children too young to be in school during their time in shelter but who enrolled in DOE subsequently. Because I am interested in the contemporaneous and short-term effects of shelter policy, my interest is in the first group.

Even restricting the match sample to age-relevant individuals, the panel nature of the data guarantees a number of irrelevant matches. A non-trivial share of household heads age 18-21 (group 2 above) are, in fact, heads of household who previously completed their DOE careers (given that DOE records extend back to 2005-06). Thus, I trim the match sample by eliminating all matches involving heads of household. Note that, by design, this also excludes all in-school heads of household, on grounds that my primary interest is in outcomes among minor students; adult students with dependents can reasonably be expected to be subject to different, potentially confounding, dynamics. In a similar way, I drop all matches where a homeless child in question is too young to be in school during a homeless spell (group 3
above); these children match due to enrollment in DOE during a subsequent post-shelter year.

Table A. 6 details the match results by birth year, focusing specifically on children aged $5-18$ during a shelter stay. Overall, 64,728 of 74,058 unique candidate students ( 87 percent), accounting for 78,465 of 88,582 student-homeless-episodes present in the DHS data ( 89 percent), have successful DOE matches. For students in the "core" birth (calendar) years of 1995-2008, the match rate is 90 percent or greater; these children are in their prime schooling years during the 2010-16 period that comprises the homelessness window. As expected, match rates are lower for older and younger children. ${ }^{5}$

The upshot of this considerable data processing effort is an unprecedented chronicle of student homelessness, detailing students' educational histories in the context of their families' homelessness experiences, as well as their characteristics, composition, labor market experiences, and public benefit use. I discuss the key variables used in the analysis in Section 3.

For most of the paper, I focus a subset of these observations in order to sharpen the analysis. These sample refinements are summarized in Table A. 5 and discussed in Section 3.

## A. 4 Complete Sample

Beyond the core dataset of homeless students, I also create a second broader dataset inclusive of all students in all available school years. I refer to this as the "complete" data. As shown in Table A.7, it spans school years 2010-2015 and contains 6,798,801 student-school-year observations across 2,177 unique schools.

The purpose of the complete data is to compare homeless students with their housed peers, which provides a frame for interpreting results. To do so, I impose the sequential sample restrictions given by row in Table A.7, arriving at a "complete sample" defined analogously to my main analytical sample and consisting of 4 million student-school-years. Because the homelessness data spans CY2010-2016 shelter entries, students who entered shelter prior to CY2010, and remained in shelter in subsequent school years, are not identified as homeless. This will cause some degree of attenuation bias in housed-homeless contrasts, particularly in the early years of the data. However, because the average length of a homeless spell for students in my sample is just over a year, comparisons from 2011 on should be mostly unaffected.

I also use the complete data to construct school-level covariates for the main analysis.

[^2]With the exception of normalized test scores (for which I used the 4 million student-schoolyears in the complete sample as the reference population), I do not impose sample restrictions when defining school-level covariates so as to capture the most comprehensive school-level characteristics.

## A. 5 Geographical Data Management

Because geography is central to this paper, it is worth highlighting the software that facilitates the analysis. After cleaning and standardizing addresses, I geocode shelter addresses and families' pre-shelter residential ("home") addresses using the New York City Department of City Planning's Geosupport Desktop Edition (Version 17.1) (NYC Department of City Planning, 2017).

Shelter addresses come from a pair of DHS CARES "Facilities" queries that together detail shelter addresses (in the case of multi-site shelters, at the individual shelter unit level), as well as daily-level capacity and occupancy.

School addresses come from the NYC Department of Education's annual school location geocode files for school years 2012-13 to 2017-18, which are publicly available through NYC Open Data (NYC Department of Education, 2017).

Home-to-shelter and home-to-school distances, as well as linear school-shelter distance, are calculated with the Pythagorean theorem, using geocoded X-Y coordinates. ${ }^{6}$ School-to-shelter distances - my primary treatment measure - are calculated using Google Maps Platform's Distance Matrix API (Google, 2023).

## A. 6 Treatment Definition Details

While the DHS data contains exact dates of shelter stay, DOE's preferred source of school enrollment, the June Biographical data, reports only students' end-of-year status. Thus, using this field is inappropriate for assigning schools of origin. ${ }^{7}$

To address this concern, I turn to the DOE Transactions data and employ the following algorithm to identify each student's original school for each school year.

If a student's first school year is present in the data, they are assigned the school of their first-ever DOE admission from the transactions data for this school year. Students who entered DOE prior to 2005 are assigned their June 2005-06 school.

[^3]Next, students with "structural" school changes-that is, scheduled promotion into middle school (usually grade 6) or high school (usually grade 9) - are assigned the school of first transaction for that school year.

For all remaining school years (those which are neither a student's first in DOE nor entail structural changes), students are assigned the school borough of the prior June (i.e., the default assumption is school stability). If prior year school is missing, they are assigned the school of first admission in the current school year; if transactions records are also missing, they are assigned the end-of-year June school.

By assigning each student the earliest possible school with which they are associated in each school year, the risk of mechanical treatment is minimized.

A second issue is that, while the school-shelter nexus is the most policy relevant treatment definition-the explicit goal, after all, is to keep children in their "home" schools-it is not the only sensible way to define treatment. For each student, there are three relevant locations: home (pre-shelter residence), school, and shelter. A function of any of these three pairwise links can identify a coherent treatment concept.

I choose to focus of the school-shelter link for two reasons. First, as proxies for genuine "home" locations, school identities are likely to be more stable and less error prone than address of prior residence, as the latter is both self-reported and more transient, given frequent moves among families at-risk of homelessness. Second, the main interest of this paper is the effect of shelter proximity on educational outcomes, so the relevant distance is that between shelter and school, regardless of prior residence. In practice, there is substantial overlap between the treatment concepts.

Finally, I define treatment at the level of the individual student, rather than for the family as a whole. Although the official policy considers an entire family treated if it is placed in the borough of its youngest child's school, older siblings do not necessarily attend schools in the same boroughs. Untreated students in "treated" families will dilute the effects of proximity, so I focus on the personal measure. In practice, it is rare for siblings to have very different commutes.

## B Supplementary Results

## B. 1 Assessing the Parallel Trends Assumption of Difference-inDifferences

The credibility of DID rests fundamentally on the parallel trends assumption, so Figure A. 14 assesses pre-trends in student outcomes for the subsample of K-8 graders observed at least
three years prior to shelter entry. I obtain point estimates and pointwise standard errors (indicated by bars) by running event study regressions of the following form:

$$
\begin{equation*}
Y_{i t}=\alpha_{i}+\phi_{r}+\sum_{\substack{r \in \\\{-2,-1,1\}}}\left(\mathbf{1}\left\{R_{i r}=r\right\} \times \mathbf{1}\left\{D_{i 1}^{B}=1\right\}\right) \rho_{r}+v_{i r} \tag{1}
\end{equation*}
$$

where outcome $Y$ for student $i$ in year $t$ is function of individual fixed effects $\left(\alpha_{i}\right)$, time fixed effects $\left(\phi_{r}\right)$, and interaction between the indicator for out-of-borough treatment group membership $D_{i 1}^{B}=1$ and a set of indicators for time relative to the year prior to shelter entry, $R_{i t}=t-\left(E_{i}+1\right)$, where $E_{i}$ denotes $i$ 's school year of shelter entry, and period $r=0$ (the year immediately preceding shelter) entry is the omitted baseline. Standard errors, $v_{i t}$, are clustered by family group. Following best practice (Roth et al., 2023; Rambachan and Roth, 2023; Freyaldenhoven et al., 2021), I also estimate uniform confidence bands (denoted by spikes) and and report the Rambachan and Roth (2023) $\bar{M}$ statistic, which gives the multiple by which post-treatment violation of parallel trends would have to exceed the pretreatment maximum for the results to be invalidated.

In short, there are no (even pointwise) statistically significant pre-trends, but-to preview main DID results - there are clear increases in absences and school changes among students placed in shelters outside of their school boroughs. The post-treatment estimates for these outcomes are large enough to be tolerant of parallel trends violations double that of the largest pre-treatment violation. Test scores and promotion exhibit neither pre- nor posttrends. Figure A. 15 provides a complementary analysis for distance treatment.

## B. 2 The Natural Experiment and Student Fixed Effects Robustness

Table A. 9 assesses commute distance treatment coefficient stability across a range of covariate specifications, starting with no covariates and building up to the school and shelter FE specification. Covariates have little impact on the estimates, lending additional support to the quasi-random shelter assignment assumption.

Table A. 10 considers several alternative treatment measures: linear distance (Column 2), commute distance with the walk-transit threshold reduced to 0.5 miles (Column 3), transit distance exclusively (Column 4), walk distance exclusively (Column 5), and commute time (in minutes) (Column 6). Aside from innocuous scale effects (e.g., the commute distance mean is 50 percent larger than the linear distance mean), the results are not sensitive to treatment definition. As might be expected, at treatment means, commute time has a larger
impact on student outcomes than does distance. Compared to hypothetical students with no commutes, students with 46 -minute commutes are: absent 2.4 more days, 14.6 pp more likely to change schools, and score $0.03 \sigma$ less in math.

Table A. 11 tests for selection effects by checking the sensitivity of results to alternative sample restrictions. In particular, one might worry that since families are neither required to accept shelter placements nor to remain in them, families with unfavorable placements may leave sooner and/or try to negotiate better assignments. To address these concerns, Column 2 limits the sample to students remaining in their initial shelter assignments (to guard against within-shelter moves) ${ }^{8}$; Column 3 limits the sample to students remaining in shelter at least 30 days (to guard against abbreviated spells); Column 4 keeps each student's first-observed spell only (to guard against "shopping around"); Column 5 includes outliers whose commute distances are at or above the 95th percentile; and Column 6 includes all of the preceding sample modifications at once. Comfortingly, results are generally similar or larger (in absolute value) in the alternative samples.

Table A. 12 repeats Table 1 for several alternative definitions of proficiency among 3-8 graders. Rows $1-3$ use a binary measure that defines proficient as scoring level 3 or 4 and not missing the test. The next three rows measure proficiency only among test takers, omitting students who miss tests. Rows 7 and 8 use numeric "scale" scores. The results are consistent with the main analysis. Overall proficiency decreases by about 10 percent with borough-level distance changes.

## B. 3 Additional Heterogeneity Analysis

It seems clear that homeless students benefit from proximity, on average. But the methods and models employed in the main analysis are restrictive in the sense that they estimate a single parameter for an entire population. Given scarcity - not every student can be assigned to their first-best school (or to their first-best place of residence)—it is important to understand who (if anyone) benefits most from proximity to school and why. Tables 3 and A.14A-A.14E conduct a thorough heterogeneity analysis by repeating the main OLS estimating equation (Table 1, Column 2) separately for subgroups split by characteristics of interest. In these tables, columns index outcomes, horizontal panels denote characteristics, and individual rows divide the sample into subgroups defined by levels of the panel's characteristic. As before, each cell gives the coefficient on commute distance, along with the clustered standard error and sample size. The section for each characteristic also contains a formal test for differences in mean treatment effects across levels, and reports these dif-

[^4]ferences, as well as associated standard errors and p-values. For binary characteristics, the comparison is between the two levels; for ordered categorical variables, the comparison is between the highest and lowest levels ("unknowns" are excluded).

Table 3 is discussed in the main text. Tables A.14A-A.14D explore how treatment effects vary (or not) among a variety of other student and family characteristics. There is essentially no statistically meaningful heterogeneity among across these characteristics.

In contrast, Table A.14E provides some evidence that there is heterogeneity according to which sorts of schools students attend. In particular, attendance treatment effects are larger ( 0.214 days/mile vs. 0.137 days/mile) for students whose schools of origin have above median absences (as measured in the complete sample of homeless and housed K-8 graders). However, this finding is not entirely robust: the magnitude is qualitatively similar, but imprecisely measured when the sample is split according to absence rates and shares of students changing schools. On the other hand, there is also evidence that students switching into worse schools (as measured by quartile of the change in standardized days absent from beginning-to-end-of-year schools) as more elastic with respect to distance. Students in the fourth (worst) quartile of absence changes see absences increase by 0.238 days/mile, compared to an (imprecise) 0.089 days/mile among first quartile students. In tandem, Table A. 15 shows that when homeless students change schools, they, on average, change into schools that are modestly worse - but this effect decreases with distance. In other words, the further is a student's placement from their school of origin, the better the chance they have to switch into a (somewhat) better school.

Fittingly for a placed-based policy, a final dimension of heterogeneity to consider is the geographic distribution of treatment effects. Figures A.16-A. 19 depict the results of subsample regressions for days absent, school change, and math and English test scores, respectively, estimated individually within each school district.

The geographic pattern differs by outcome. The largest effects of commute distance on attendance occur in remote boroughs (Staten Island and the Bronx) or in the remote parts of boroughs (South Brooklyn, Northeast Manhattan, and Eastern Queens). For school changes, geographically isolated Staten Island remains a high responder, but the other places where school change effects are most pronounced are core areas of Brooklyn, Manhattan, and Queens. Similarly, math (and to a lesser extent, English) test scores appear most impacted in places where attendance effects are small (lower Manhattan, Queens, and mid-Brooklyn).

One explanation for this discrepancy is that absences and school changes may, in some sense, be substitutes. Students who opt change schools upon entering shelter may miss fewer days and consequently experience better performance. However, it is important not to read too closely into the geographic results, as effect estimates are not especially precise in many
school districts.

## B. 4 Mechanisms Analysis

Having shed some light on who benefits (everyone, but especially those situated very near their schools), another key question is why - what are some of the channels through which proximity effects operate?

One potentially important channel is through the mechanism of school change. Changing schools is the outcome most affected by proximity, so it is reasonable to ask whether school change mediates other observed outcomes. Of course, changing schools is also potentially endogenous, so any mediating correlations mobility may have are best interpreted as associations.

Table A. 16 provides this analysis. It repeats the main OLS specification (Table 1, Column 2), but interacts an indicator for school change with commute distance. Columns index outcomes, and the rows list the main and interaction effects of commute distance and school change. ${ }^{9}$ While these results should not be given causal interpretation (a decision to change schools is not random), they are suggestive. As before, longer commutes are associated with worse outcomes (an additional 0.21 absences/mile). Unsurprisingly, school change (and the disruption that comes along with it) are significantly associated with adverse outcomes-an increase in 2.7 days absent and drops of $0.08 \sigma$ in math and $0.03 \sigma$ in English. Interestinglyand in keeping with the intuition about the geographical dispersion of treatment effectschanging schools reduces the adverse impact of commute distance on attendance by about half ( 0.093 days or 0.06 pp per mile). Whether a student is net better or worth off after a move depends on circumstances; the simple model here suggests a break-even commute distance of 8.8 miles, beyond which school changes are absence-minimizing. However, there does not seem to be an overall effect on tests scores.

Another potential channel through which the effects of distance may be transmitted is through distance's effect on homelessness outcomes. Housing instability and homelessness are associated with worse educational outcomes (though as the summary statistics on prior year school outcomes emphasize, homeless students' educational challenges predate shelter entry), so understanding the direct impact of distance on homelessness is important for policy. Hence, Table A. 17 repeats Table 1 for homelessness outcomes.

The results are intuitive but surprising. Distant placements reduce shelter stays. The effect size is large-about 1.2-3.0 fewer days/mile for overall stays and 0.3-0.5 fewer days/per mile during the school year of shelter entry. At distances at the scale of changes-in-borough,

[^5]distant placements reduce the lengths of overall shelter stays by about 22-43 days, or 59 percent of the average length of stay of 458 days. However, distant placements do not appear to change the likelihood of homelessness in subsequent school years. These results are consistent with the more detailed analysis of whole-family impacts of neighborhood-based shelter placements in Cassidy (2020).

Continuing this theme, Table A. 18 studies the persistence of treatment effects. It repeats Table 1, Columns 1-3, for students in each of the two following school years (i.e, if $t$ is the school year of shelter entry, these are years $t+1$ and $t+2$ ). There does seem to be some enduring impact of shelter assignment on school stability, at least in the short term. Students continue to be about $0.4 \mathrm{pp} /$ mile more likely to change schools in year $t+1$, and about $0.14 \mathrm{pp} /$ mile more likely to change schools in year $t+2$, even as the baseline probability of changing schools diminishes by a third. On the other hand, shelter proximity does not appear to have much of a short-term legacy in terms attendance and test scores.

| 6 | 28,976 | 18,081 |  |  | 7,082 | 3,503 |  |  |
| 7 | 21,894 | 14,578 |  |  | 6,489 | 3,804 |  |  |
| 8 | 15,405 | 10,774 |  |  | 6,192 | 4,096 |  |  |
| 9 | 9,213 | 6,678 |  |  | 6,708 | 4,761 |  |  |
| 10 | 2,505 | 1,917 |  |  | 2,106 | 1,603 |  |  |
| 11 | 399 | 314 |  |  | 354 | 277 |  |  |
| 12 | 45 | 37 |  |  | 45 | 37 |  |  |
| Total | 348,578 | 175,540 | 29,353 |  | 70,631 | 26,660 | 26,660 |  |

Columns $1-3$ give the number of student-school-years (which is the unit of observation) present in the data for students observed the row-delineated number of times. Columns $4-6$ give the unique students observed the row-delineated number of times. Note that for observations, rows are cumulative in the sense that all being observed $n$ times implies being observed $n-1$ times as well. However, for students, rows are mutually exclusive in the sense that students in row $n$ are observed $>n-1$ but $<n+1$ times. "All" refers to the unrestricted dataset of student school years observed for students in grades K-8. "Main: All" refers to students in the main sample across the full set of school years observed, 2005-2016. "Main: Sample" refers only to student observations included in the main sample. Main sample consists school years of shelter entry among homeless public (non-charter) school K-8 students during school years 2010-2015 (who entered shelter during calendar years 2010-2016). To be included in the main sample, these students must also be enrolled in DOE 180 days prior to shelter entry and have non-missing attendance data; students whose shelter assignments are in the top five percentiles of commute distance from school (distance outliers) are also excluded.

Table A.2A: Summary Statistics by Housing Status, Grades K-8, 20102015

|  | Housing Status |  |  |

This table compares average characteristics of housed and homeless students. Rows list outcomes and covariates. Column one gives housed means. Column 2 gives homeless means. Column 3 gives the raw differences, estimated from separate bivariate regressions of each covariate on an indicator for homeless. Unit of observation is student-schoolyear. Students are classified as homeless during the school years in which they spend any time in homeless shelter; students not in shelter during a given school year are classified as housed. Sample consists of all NYC DOE K-8 grade students with nonmissing admissions data during school years 2010-2015. Standard errors clustered at the family group level are given in parentheses. Percent changes relative to housed student means are given in brackets.

Table A.4A: Description of Covariates

| Variable | Description |
| :--- | :--- |

A. Student and Family Covariates

## A1. Base Covariates

| School Year Fixed Effects | 6 dummies for years 2010-11 to 2015-16. |
| :--- | :--- |
| Shelter-Entry-Month Fixed Effects | 12 dummies for January-December. |
| School Borough Fixed Effects | 5 dummies for school county origin (pre-shelter). |
| Grade Level Fixed Effects | 9 dummies for grades K-8. |

## A2. Placement Covariates

| Family Students | Integer count of students in a family. |
| :---: | :---: |
| Family Non-Students | Integer count of non-student family members. |
| Partner Present | Dummy for head-of-household partner present in shelter. |
| Pregnant | Dummy for pregnant family member. |
| Health Issue | Dummy for family member with physical, mental, or substance abuse issue. |
| Student with Disability | Dummy for the presence of an Individualized Education Program (IEP). |
| District 75 | Dummy for attending a D75 school. District 75 is a special non-geographical designation given to programs providing special services to students with significant disabilities. |
| Domestic Violence | Dummy for DV as reason for shelter eligibility. |
| Homeless Prior School Year* | Dummy for whether a student was homeless in the previous school year. |
| Pre-shelter School Distance* | Ventiles ( 20 groups) of linear distance between student's school and last residential address prior to shelter. |
| A3. Student Covariates |  |
| Female | Dummy for female gender. |
| English Language Learner (ELL) | Dummy for English learner status. |
| Non-English Speaking | Dummy for non-English speaking home. |
| NYC Native | Dummy for NYC birthplace. |
| Foreign Born | Dummy for birthplace outside of the United States. |
| Youngest School-Aged Child | Dummy for whether a student is the youngest student in the family. |
| Age | Quadratic in monthly age at December 31 of a given school year. |
| Race Fixed Effects | Dummies for Black, Hispanic, White, Asian, Native American, multi-racial, and unknown. |

This table describes all of the covariates included in the main analysis. Base covariates and placement covariates together comprise "balance test" covariates, conditional upon which shelter assignment is quasi-random. Collectively, student and family covariates (A) and student prior school year covariates (B) comprise "main" covariates, which define the baseline empirical specification. All levels of fixed effects and categorical variables are described for completeness, but base categories are omitted from regressions to avoid multicollinearity.
*All prior school year student covariates are appended with an additional "unknown" category to avoid dropping students with missing data.
${ }^{+}$School covariates are calculated annually for each school using the 6.8 million student-school year observations comprising the complete DOE data (without imposing any sample restriction).

Table A.4B: Description of Covariates

| Variable | Description |
| :---: | :---: |
| A4. Family Covariates |  |
| Female | Dummy for female head-of-household. |
| Employed | Dummy for head employed during the year prior to shelter entry. |
| SNAP | Indicator for whether head had active Supplemental Nutrition Assistance Program case at shelter entry. |
| Cash Assistance | Indicator for whether head had active public assistance case at shelter entry. |
| Age | Quadratic in head age at time of shelter entry. |
| Log Average Quarterly Earnings | The natural logarithm of average quarterly earnings in the year prior to shelter entry, plus one dollar. |
| Educational Attainment Fixed Effects | Dummies for less than high school, high school graduate, some college or more, and unknown. |
| Shelter Type Fixed Effects | 4 dummies for type of initial shelter assignment: Tier II, cluster unit, commercial hotel, and other. |
| Eligibility Fixed Effects | 6 dummies for shelter eligibility reason: eviction, overcrowding, housing conditions, domestic violence, other, and unknown. |
| A5. School Covariates ${ }^{+}$ |  |
| Enrollment | School-year-specific count of student enrollment. |
| Female Share | School-year-specific female student mean. |
| Black Share | School-year-specific Black student mean. |
| White Share | School-year-specific White student mean. |
| Hispanic Share | School-year-specific Hispanic student mean. |
| Asian Share | School-year-specific Asian student mean. |
| Native American Share | School-year-specific Native American student mean. |
| Multi-Race Share | School-year-specific multi-race student mean. |
| English Language Learner Share | School-year-specific English language learner student mean. |
| NYC-Native Share | School-year-specific NYC-native student mean. |
| Foreign-Born Share | School-year-specific foreign-born student mean. |
| Students with Disabilities Share | School-year-specific students with IEP mean. |
| Poor Share | School-year-specific mean of students receiving free or reducedprice lunch. |
| Homeless Share | School-year-specific homeless student mean. |

## B. Student Prior School Year Covariates*

| Days Absent | Ventiles of prior year days absent. |
| :--- | :--- |
| Absence | Ventiles of prior year absence rates. |
| School Change | Dummy for prior year school change. |
| School Change | Dummy for prior year proficiency in English and math. |
| Promoted | Indicator for promoted in the prior year. |

## C. School and Shelter Fixed Effects

| School Fixed Effects | 1,148 dummies for school of origin. |
| :--- | :--- |
| Shelter Fixed Effects | 226 dummies for initial shelter assignment. |

[^6]Table A.5: Sample Step-Down Table

| Refinement | Obs | Homeless <br> Share |
| :--- | :---: | :---: |
| All Data | 479,914 | 0.37 |
| In-School (Grades K-8) | 348,578 | 0.31 |
| School Years 2010-2015 | 210,777 | 0.43 |
| Excluding Charter Schools | 194,405 | 0.43 |
| Non-Missing Attendance | 191,756 | 0.43 |
| Enrolled in DOE Prior to Shelter | 62,160 | 1.00 |
| First School Year of Shelter Entry | 31,886 | 1.00 |
| Excluding Commute Distance Outliers | 29,353 | 1.00 |

This table shows the path from the full data to the main analysis sample. Sample refinements are cumulative: each row imposes an additional restriction on the row above it. Data are from matched NYC Department of Homeless Services (calendar years 2010-2016) and Department of Education (school years 2005-2016) administrative records.

Table A.6: Match Stats: Students Age 5-18

|  | Students |  |  |  | Episodes |  |  |

| Total | 74,058 | 64,728 | 0.87 | 88,582 | 78,465 | 0.89 |  |

This table shows the results of probabilistic linkage of Department of Homeless Services (calendar year 2010-2016) and Department of Education (school year 2005-2016) administrative data. The sample universe is DHS family shelter entrants from calendar years 2010-2016. Candidate students are matched on first name, last name, date of birth (month and year), and sex. The statistics presented here encompass children ages $5-18$ at some point during their homeless shelter spell.

Table A.7: Complete Sample Step-Down Table

| Refinement | Obs | Homeless <br> Share |
| :--- | :---: | :---: |
| All Data | $6,798,801$ | 0.02 |
| In-School (Grades K-8) | $4,396,886$ | 0.02 |
| School Years 2010-2015 | $4,396,886$ | 0.02 |
| Excluding Charter Schools | $4,037,283$ | 0.02 |
| Non-Missing Attendance Outcomes | $3,990,057$ | 0.02 |

This table shows the path from the complete Department of Education data to the "complete" sample, which is analogous to the main sample but also includes housed students. Sample refinements are cumulative: each row imposes an additional restriction on the row above it. Data are from matched NYC Department of Homeless Services (calendar years 2010-2016) and Department of Education (school years 2005-2016) administrative records.

| Obs. | 16,150 | 13,203 |  |  |  |

This table provides a balance test of key student and family characteristics, all of which are covariates in the main analysis, across both borough and commute distance treatment definitions for the main sample. Rows list covariates. Column one gives in-borough means. Column 2 gives out-of-borough means. Column 3 gives the raw differences, estimated from separate bivariate regressions of each covariate on out-of-borough treatment. Columns 4 and 5 assess covariate balance by continuous commute distance (in miles), obtained by regressing each covariate separately on a linear (Column 4) or quadratic (Column 5) model in commute distance, controlling for balance test covariates (i.e., features conditional upon which shelter assignment is quasi-random). Reported contrasts compare covariates at the in-borough ( 3.9 miles) and out-of-borough ( 13.5 miles) commute distance means. Standard errors clustered at the family group level are given in parentheses. P-values for tests of null contrasts are given in braces. Percent changes relative to in-borough means are given in brackets. The first row summarizes commute distance means for students placed in shelters in and out of their school boroughs.

This table provides a balance test of key student and family characteristics, all of which are covariates in the main analysis, across both borough and commute distance treatment definitions for the main sample. Rows list covariates. Column one gives in-borough means. Column 2 gives out-of-borough means. Column 3 gives the raw differences, estimated from separate bivariate regressions of each covariate on out-of-borough treatment. Columns 4 and 5 assess covariate balance by continuous commute distance (in miles), obtained by regressing each covariate separately on a linear (Column 4) or quadratic (Column 5) model in commute distance, controlling for balance test covariates (i.e., features conditional upon which shelter assignment is quasi-random). Reported contrasts compare covariates at the in-borough ( 3.9 miles) and out-of-borough ( 13.5 miles) commute distance means. Standard errors clustered at the family group level are given in parentheses. P-values for tests of null contrasts are given in braces. Percent changes relative to in-borough means are given in brackets.

Table A.9: Coefficient Stability: Covariate Specification Robustness

|  | None | Base | Balance | No Prior | Main | Shelter + |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| School FE |  |  |  |  |  |  |

This table assesses the sensitivity of Table 1 results to alternative covariate specifications. Outcomes are listed in rows. Analytical specifications are indexed by column. Treatment is continuous school-shelter commute distance (in miles). Unit of observation is a student school year. Each cell reports the coefficient on commute distance from a separate OLS linear regression of the row-indexed outcome on commute distance and the covariates described at the bottom of the table. Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors.

| Units | Miles | Miles | Miles | Miles | Miles | Minutes |
| Student and Family Covariates | Yes | Yes | Yes | Yes | Yes | Yes |
| School and Shelter FE | No | No | No | No | No | No |

This table assesses the robustness of Table 1 results to alternative treatment measures. Outcomes are listed in rows. Treatment measures are indexed by column. Unit of observation is a student school year. Each cell reports the coefficient on treatment from a separate OLS linear regression of the row-indexed outcome on treatment and the main covariate specification from Table 1. Column 1 repeats Column 2 from Table 1 for reference, using the main treatment definition of continuous school-shelter commute distance (in miles). Column 2 defines treatment as linear (Cartesian) distance (in miles). Column 3 uses commute distance, but changes the walk threshold to $\leq 0.5$ miles. Column 4 uses public transit distance (in miles). Column 5 uses walking distance (in miles). Column 6 uses commute time (in minutes). Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors. The last set of numerical rows gives the treatment mean and standard deviation.

This table addresses potential concerns about family self-selection into shelter assignments by assessing the robustness of Table 1 results to alternative samples. Outcomes are listed in rows. Samples are indexed by column. Unit of observation is a student school year. Each cell reports the coefficient on continuous commute distance (in miles) from a separate OLS linear regression of the row-indexed outcome on commute distance and the main covariate specification from Table 1 . Column 1 repeats them main sample results from Column 2 of Table 1 for reference. Column 2 limits the main sample to students whose primary shelter (i.e., shelter of longest stay) during their shelter spell is their intial shelter, thus excluding students from families with major shelter changes. Column 3 limits the main sample to students whose shelter stays are at least 30 days, thus excluding students from families with short stays. Column 4 limits the main sample to students' first observed homeless spell (post-2010), thus excluding subsequent returns to shelter. Column 5 expands the main sample to include commute distance outliers - that is, it includes students placed in the 95 th + percentiles. Column 6 includes all of the preceding sample modifications at once. Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors.

Outcomes are given in rows. Estimation methods are indexed by column. Unit of observation is a student school year. Each cell reports the average treatment effect on the treated (ATT) of the supercolumn-indexed treatment on the row-indexed outcome from a separate estimation using the column-indexed method. The sample and covariates for each method are summarized at the bottom of the table. Columns 1 and 4 repeat the main OLS specification from Table 1 for the main sample subsample of the DID sample (i.e., shelter entry years only), corresponding to Table 1, Columns 6 and 2 , respectively. Columns 2 and 4 give the standard two-way fixed effects DID estimates, controlling for student and relative time fixed effects. Columns 3 and 6 limit the DID sample to the students observed continuously for relative-time school years, $-2 \leq R \leq 1$, where $R=1$ in the treated school year and estimate the TWFE model for this sub-subsample; these are the students who are included in the pre-trends analysis. Each cell in Columns $1-3$ reports results for treatment defined as an indicator for out-of-school-borough shelter placement. Each cell in Columns 4-6 reports the coefficient on continuous linear school-shelter commute distance (in miles). Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors.

Table A.14A: Heterogeneity Analysis

This table conducts a heterogeneity analysis by repeating the main analysis from Table 1 for subgroups. Unit of observation is a student school year. Outcomes are listed in columns. Rows index the characteristics and levels defining the subsamples among which the heterogeneity analysis is conducted. Each cell in a characteristic-level row reports the coefficient on continuous commute distance (in miles) from a separate regression of the column-enumerated outcome on commute distance and the main covariate specification from Table 1 for the subsample defined by the characteristic-level row. Standard errors clustered by family group are given in parentheses. Sample sizes are given in the third row of each cell. Difference in Means row for each characteristic gives the difference in coefficients, standard errors of the differences (in parentheses), and p-values (in the third row). For binary characteristics, the comparison is between the two levels; for ordered categorical variables, the comparison is between the highest and lowest levels.

This table conducts a heterogeneity analysis by repeating the main analysis from Table 1 for subgroups. Unit of observation is a student school year. Outcomes are listed in columns. Rows index the characteristics and levels defining the subsamples among which the heterogeneity analysis is conducted. Each cell in a characteristic-level row reports the coefficient on continuous commute distance (in miles) from a separate regression of the column-enumerated outcome on commute distance and the main covariate specification from Table 1 for the subsample defined by the characteristic-level row. Standard errors clustered by family group are given in parentheses. Sample sizes are given in the third row of each cell. Difference in Means row for each characteristic gives the difference in coefficients, standard errors of the differences (in parentheses), and p-values (in the third row). For binary characteristics, the comparison is between the two levels; for ordered categorical variables, the comparison is between the highest and lowest levels.

Outcomes are listed in rows. Analytical specifications are indexed by column. Unit of observation is a student school year. Column 1 gives outcome means (standard deviations in parentheses). Each cell in Columns 2-5 reports the coefficient on continuous school-shelter commute distance (in miles) from a separate OLS linear regression of the row-indexed outcome on commute distance (i.e., treatment) and the covariates described at the bottom of the table. Each cell in Columns 6-9 reports analogous results for treatment defined as an indicator for out-of-school-borough shelter placement. Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors. Percent changes from outcome means are given in brackets. All results are for the main sample, though only a subset of observations contribute to identification in the specifications with school, shelter, and, especially, student fixed effects.

Table A.16: Mediating Assocation of School Changes with Commute Distance

This table explores school changes as a potential mediator for the effects of commute distance on student outcomes. Outcomes are listed in columns. Each column is a separate regression of the given outcome on continuous commute distance (in miles) interacted with an indicator for change of school, controlling for main covariates. Rows report the coefficients, respectively, of commute distance, school change, and their interaction. Results should be interpreted as associations, since school changes following shelter entry are potentially endogenous. Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors.

This table repeats Table 1 for homelessness outcomes. Outcomes are listed in rows. Analytical specifications are indexed by column. Unit of observation is a student school year. Column 1 gives outcome means (standard deviations in parentheses). Each cell in Columns 2-5 reports the coefficient on continuous school-shelter commute distance (in miles) from a separate OLS linear regression of the row-indexed outcome on commute distance (i.e., treatment) and the covariates described at the bottom of the table. Each cell in Columns 6-9 reports analogous results for treatment defined as an indicator for out-of-school-borough shelter placement. Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors. Percent changes from outcome means are given in brackets. All results
are for the main sample, though only a subset of observations contribute to identification in the specifications with school, shelter, and, especially, student fixed effects.

This table repats the analysis of Table 1, Columns 1-3 for for outcomes in the school year following the shelter entry school year(year $t+1$; Columns 1-3) and two years following shelter entry (year $t+2$; Columns 4-6), where $t$ is the school year of shelter entry. Outcomes are listed in rows. Analytical specifications are indexed by column. Treatment is continuous school-shelter commute distance (in miles). Unit of observation is a student school year. Each cell reports the coefficient on commute distance from a separate OLS linear regression of the row-indexed outcome on commute distance and the covariates described at the bottom of the table. Columns 1 and 4 give sample means. Columns 2 and 5 feature the main covariate specification. Columns 3 and 6 include school and shelter fixed effects. Standard errors clustered by family group are given in parentheses. Sample sizes are given below standard errors.

## E Supplementary Figures

Figure A. 1

NYC DOE ELA Standardized Score, Grades 3-8, 2010-2015

New York State grade 3-8 English Language Arts scaled test scores are normalized by year and grade within the NYC Department of Education student population; thus, point estimates are in standard deviation units. Homeless is defined as residing in Department of Homeless Services shelter; housed is defined as all other students. Sample covers the 2010-2015 school years among 3-8 public school students not in charter schools.

Figure A. 2

NYC DOE Math Standardized Score, Grades 3-8, 2010-2015

Housed N=2,403,703 ; Homeless N=42,725
New York State grade 3-8 math scaled test scores are normalized by year and grade within the NYC Department of Education student population; thus, point estimates are in standard deviation units.Homeless is defined as residing in Department of Homeless Services shelter; housed is defined as all other students. Sample covers the 2010-2015 school years among 3-8 public school students not in charter schools.

Figure A. 3

NYC DOE Proficiency, Grades 3-8, 2010-2015
Comparison by Homeless Status

Housed $N=2,551,297$; Homeless $N=47,724$

Proficient is defined as scoring level 3 or 4 on both English and math New York State tests. Students missing tests are considered not proficient. Homeless defined as residing in Department of Homeless Services shelter; housed is defined as all other students. Sample covers the 2010-2015 school years among 3-8 public school students not in charter schools. New Common Core testing standards were introduced in 2012.

Figure A. 4

Housed $N=3,084,780$; Homeless $N=67,331$

This figure gives the probabilities of students changing schools within a given school year. Homeless is defined as residing in Department of Homeless Services shelter; housed is defined as all other students. Sample covers the 2011-2015 school years among K-8 public school students not in charter schools. 2010 is excluded because 2009 homeless data is unavailable.

Figure A. 5

NYC DOE Promotion Rates, Grades K-8, 2010-2015

Housed $N=3,703,356$; Homeless $N=75,755$
This figure gives the probabilities of students being promoted during each school year. Homeless is defined as residing in DHS shelter; housed is defined as all other students. Sample covers the 2010-2015 school years among 3-8 public school students not in charter schools.

Figure A. 6

## Student Poverty Rate by School District

K-8 Main Sample

This figure depicts a choropleth map of mean poverty rates for the complete sample of primary schoolers by school district of origin, pooling school years 2010-2015. Poverty is defined as eligible for free or reducedprice lunch or public assistance. Limits of shading bins are set at $0,25,50,75,90,100$ percentiles of the mean poverty rate.

Figure A. 7

## Homeless Students by Shelter School District

 K-8 Main Sample

The figure depicts a heatmap of main sample homeless primary schoolers by school district of shelter, pooling school years 2010-2015. Limits of choropleth shading bins are set at $0,25,50,75,90,100$ percentiles of the homeless student counts.

Figure A. 8

## Prior Year Days Absent Mean by School District

|  | Days Absent |
| :--- | :--- |
| $\square$ | $20.4-22.8$ |
| $22.8-23.9$ |  |
| $23.9-25.6$ |  |
| $25.6-26.2$ |  |
| $26.2-33.6$ |  |
|  | No data |

The figure depicts a choropleth map of mean days absent for the main sample of homeless primary schoolers in the school year prior to shelter entry by school district of origin, pooling school years 2010-2015. Limits of shading bins are set at $0,25,50,75,90,100$ percentiles of prior year days absent.

Figure A. 9

## Commuting Distance Mean by School District K-8 Main Sample

The figure depicts a choropleth map of mean commute distances for the main sample of homeless primary schoolers by school district of origin, pooling school years 2010-2015. Limits of shading bins are set at 0, 25, $50,75,90,100$ percentiles of commute distances.

Figure A. 10

## Linear Distance Mean by School District

## K-8 Main Sample

(miles)
3.7-5.0
5.0-5.9
5.9-7.3
7.3-8.4
8.4-9.8

The figure depicts a choropleth map of mean linear school-shelter distances for the main sample of homeless primary schoolers by school district of origin, pooling school years 2010-2015. Limits of shading bins are set at $0,25,50,75,90,100$ percentiles of linear distance.

Figure A. 11

## Out-of-Borough Placement Rates by School District

 K-8 Main Sample

The figure depicts a choropleth map of mean out-of-borough shelter placement rate for the main sample of homeless primary schoolers by school district of origin, pooling school years 2010-2015. Limits of shading bins are set at $0,25,50,75,90,100$ percentiles of mean out-of-borough placement rate.
Figure A. 12

Quadratic
 vertical lines give covariate-adjusted means and 95 percent confidence intervals for the sample divided into 12 commute distance groups according to rounded-to-the-nearest-

 p-values presented in parentheses in that order.
Figure A. 13

## Balance Test: Outcomes

[^7]Figure A. 14
Pretrends Assessment: Borough Treatment

モI'V ә.m.8! - H

$\longmapsto$ Pointwise Cl
This figure assesses the credibility of the parallel trends assumption, with out-of-borough shelter assignment as the treatment. Point estimates and 95 percent confidence intervals are obtained from separate two-way fixed effects OLS linear regressions of each outcome (denoted by panel) on relative
 family group. Pointwise CI's are indicated by bars; uniform confidence bands are indicated by vertical lines. Outcome mean, Rambachan and Roth (2023) $\bar{M}$ statistic, sample size, and unique number of students reported below each panel.
Figure A. 15
Pretrends Assessment: Distance Treatment

$\longmapsto$ Pointwise Cl $\quad$ Uniform CB
This figure assesses the credibility of the parallel trends assumption, with change linear school-shelter distance upon shelter entry as the treatment;

 below each panel.

Figure A. 16

## Days Absent Mean Treatment Effects by School District Commute Distance Treatment; K-8 Main Sample

The figure depicts a choropleth map of average marginal effects of commute distance on days absent (in days per mile) for main sample homeless primary schoolers by school district of origin, pooling school years 2010-2015. Estimates are obtained from separate OLS linear regressions, within each school district, of days absent on commute distance, controlling for main covariates. Limits of shading bins are set at $0,25,50,75$, 90,100 percentiles of effect (coefficient) distribution. ${ }^{*} * p<0.05,{ }^{*} p<0.10$.

Figure A. 17

## School Change Mean Treatment Effects by School District Commute Distance Treatment; K-8 Main Sample

The figure depicts a choropleth map of average marginal effects of commute distance on the probability of school change for main sample homeless primary schoolers by school district of origin, pooling school years 2010-2015. Estimates are obtained from separate OLS linear regressions, within each school district, of days absent on commute distance, controlling for main covariates. Limits of shading bins are set at $0,25,50,75$, 90,100 percentiles of effect (coefficient) distribution. ${ }^{*} * p<0.05,{ }^{*} p<0.10$.

Figure A. 18

## ELA Std. Score Mean Treatment Effects by School District Commute Distance Treatment; K-8 Main Sample

The figure depicts a choropleth map of average marginal effects of commute distance on normalized 3-8 grade NYS test scores (in standard deviations per mile) for main sample $3-8$ grade homeless primary schoolers by school district of origin, pooling school years 2010-2015. Estimates are obtained from separate OLS linear regressions, within each school district, of normalized test scores on commute distance, controlling for main covariates. Limits of shading bins are set at $0,25,50,75,90,100$ percentiles of effect (coefficient) distribution. ${ }^{*} * p<0.05,{ }^{*} p<0.10$.

Figure A. 19

## Math Std. Score Mean Treatment Effects by School District Commute Distance Treatment; K-8 Main Sample

The figure depicts a choropleth map of average marginal effects of commute distance on normalized 3-8 grade NYS test scores (in standard deviations per mile) for main sample $3-8$ grade homeless primary schoolers by school district of origin, pooling school years 2010-2015. Estimates are obtained from separate OLS linear regressions, within each school district, of normalized test scores on commute distance, controlling for main covariates. Limits of shading bins are set at $0,25,50,75,90,100$ percentiles of effect (coefficient) distribution. ${ }^{*} * p<0.05,{ }^{*} p<0.10$.

[^0]:    ${ }^{1}$ Due do a minor coding issue that does not affect results, 16 students in this sample potentially had their applications entered or approved outside the calendar year 2010-2016 period.
    ${ }^{2}$ DHS considers returns to shelter within 30 days of leaving to be part of the same spell.

[^1]:    ${ }^{3}$ For simplicity, I refer to the DSS/HRA data and DOL under the umbrella of "DHS" since the linkage is performed with the DHS data.
    ${ }^{4} 21$-years-of-age is also the DHS definition of child.

[^2]:    ${ }^{5}$ There are several legitimate reasons a school-age homeless child may not show up in DOE records, including moves into and out of NYC contemporaneous with homeless episodes and enrollment in parochial or private schools.

[^3]:    ${ }^{6}$ The GBAT geocoding application establishes Cartesian coordinates according to the State Plane Coordinate system, New York-Long Island zone, NAD 83, with units measured in feet.
    ${ }^{7}$ In addition, about 10 percent of homeless students originate from outside NYC during the 2010-2015 school years. I exclude these non-NYC students from the analysis.

[^4]:    ${ }^{8}$ Specifically, to students whose shelter of longest residence in a particular spell matches their initial shelter assignment.

[^5]:    ${ }^{9}$ Thus, there is one regression per column, which is different from the other result tables, which have one regression per cell.

[^6]:    This table describes all of the covariates included in the main analysis. Base covariates and placement covariates together comprise "balance test" covariates, conditional upon which shelter assignment is quasi-random. Collectively, student and family covariates (A) and student prior school year covariates (B) comprise "main" covariates, which define the baseline empirical specification. All levels of fixed effects and categorical variables are described for completeness, but base categories are omitted from regressions to avoid multicollinearity.
    *All prior school year student covariates are appended with an additional "unknown" category to avoid dropping students with missing data.
    ${ }^{+}$School covariates are calculated annually for each school using the 6.8 million student-school year observations comprising the complete DOE data (without imposing any sample restriction).

[^7]:    The figure presents a comprehensive balance test of student outcomes for the main sample, split into one panel for each characteristic. Black dots and black vertical lines give covariate-adjusted means and 95 percent confidence intervals for the sample divided into 12 commute distance groups according to rounded-to-the-nearest-two-mile commute distances. (All students with commute distances 22 miles or greater are grouped together.) Estimates are obtained from separate linear regressions of each characteristic of interest on commute distance group fixed effects (omitting the 0 -mile group as the baseline) and balance test covariates. Red and blue lines, respectively, give linear and quadratic fits (and shaded 95 percent confidence intervals) obtained from separate OLS regressions of each characteristic on continuous commute distance, controlling for balance test covariates. Dashed vertical gray lines give the in-borough (leftmost) and out-of-borough (rightmost) commute distance means. All standard errors are clustered by family group. Mean differences in characteristic means at the in- and out-of-borough commute distance means are reported under each panel, with standard errors and p-values presented in parentheses in that order.
